## Motivation

Bluetooth Low Energy (BLE) trackers are devices that can be used to locate lost items, but they are commonly misused for stalking because of their convenience and small size. Such devices include AirTags, Tiles, SmartTags, PebbleBees and Chipolos.

## Key Privacy Features

- Does not collect user login data
- Independent from any web services
- Stores all data on-device
- Does not require location permissions
- Does not block functionality if location access is denied

## Prior Work

BLE tracking alert approaches do not adequately alert users[1]. This is partially due to device incompatibilities and lack of manufacturer participation. AirGuard[2] addresses these problems, but has limitations because of the static thresholds used to evaluate risk.

BL(u)E CRAB introduces a metric-driven risk method based on dynamic thresholds derived from various risk factors.

## Risk Factors

- Time with User: Measures the duration of time a device is near the user.
- Incidence: Counts the number of "run-ins" the user has with a device.
- Distance Travelled with User: Measures the distance a device has travelled with the user.
- Area Count: Measures the amount of non-overlapping location clusters separated by a threshold distance.
- Device Proximity: Measures the device's proximity via RSSI

## How BL(u)E CRAB Works

## Screenshots

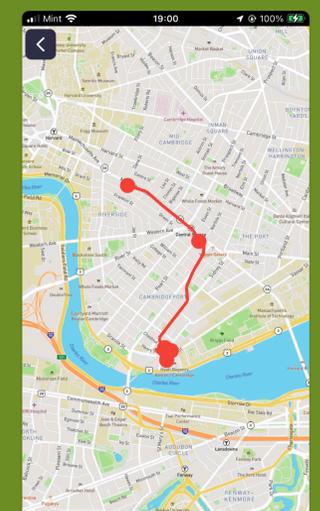

Scanner view with the scan button at the bottom

Report view with tiles for flagged devices

Device detail view displaying identifiers along with risk factors

Map of where the selected device traveled with the user

## Future Work

- Improve outlier detection and add more risk factors
- Conduct empirical analysis
- Explain why a device is suspicious in a natural language
